

Project Title: AI for Chest X-ray

Supervisor(s): Dr. Mehdi Moradi

Supervisor's Email Address: moradm4@mcmaster.ca

Supervisor's Organization: McMaster University, CAS

Description:

For our project we will be implementing an AI model for chest x-rays to identify common diseases. An AI for chest x-rays is beneficial since it can be used to save doctors time and save hospitals money by speeding up the analysis of x-rays and help give patients a faster diagnosis. The main purpose of using AI on chest x-rays would be to identify negative results or identify what diseases are present and the location of these diseases to doctors with the use of visual mapping and specific tags for the disease and location. The main stakeholders for this project will be doctors (radiologists) who will be examining the x-rays, medical imaging technologists (radiographers) who will be taking the x-rays, and the hospital administrative staff who will be sourcing the x-rays in DICOM format from PACS (Picture Archiving and Communication System) and helping with other administrative details. In terms of functionality, our project will consist of two main parts, a front-end website, and a back end for image processing through AI. Specifically, the front-end website will allow for uploads of DICOM images as it is standard in hospitals and it will return the image with tags for what disease(s) it found, as well as the image itself with highlighted locations of where it has found any disease(s). For the backend we will be training our model in python, which has a number of tools and libraries for ML. In terms of datasets for training we have identified a number of sources for chest x-rays such as Kaggle, CheXpert from Stanford and open libraries on GitHub like TorchXRayVision that combine datasets.
